# GRBs: The Very Brief Version

- Humble Beginnings: A Bomb or Not a Bomb?
  - ⇒ Vela Program
- A few hundred events, a few hundred theories
- Finally, science to the rescue
  - ⇒ Compton Gamma Ray Observatory
  - ⇒ BeppoSAX/ROTSE/HST/ (and a host of others)

# 2704 BATSE Gamma-Ray Bursts

Great debate: 1967-1997

## Summary of the Observations of Long GRBs

- A “typical” long-duration GRB lasts 20 s in  $\gamma$ -rays from keV to MeV energies
- It takes place in star-forming (spiral or dwarf irregular) galaxies, but not in ellipticals
- It takes place in a galaxy at  $z \sim 1$
- About  $10^{51} - 10^{54}$  ergs of (apparent isotropic) energy are emitted and (apparent isotropic) powers of  $\sim 10^{50} - 10^{52}$  ergs/s
- It is followed by long-lived X-ray, optical, and radio afterglow emission

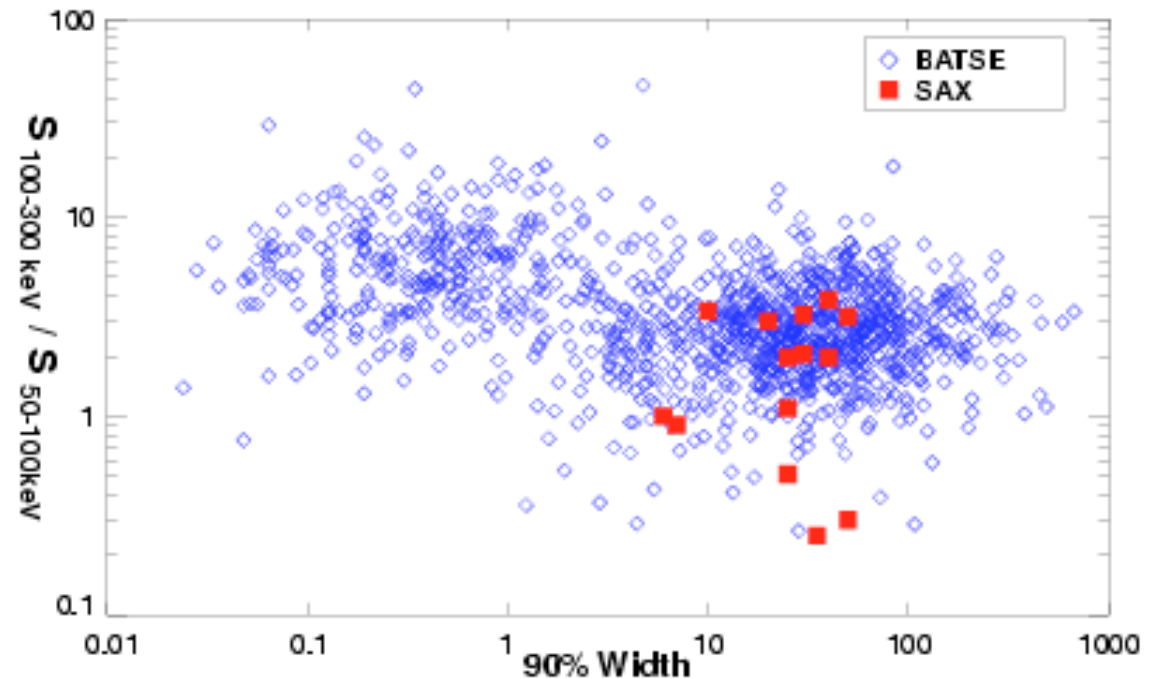

# Durations

- Two classes:

1. **Short**:  $T_{90} < 2$  s,  
harder

2. **Long**:  $T_{90} > 2$  s,  
softer

# Models for GRBs

Hypernova

Merging Neutron Stars

# Core collapse vs. Mergers

## HYPERNOVAE

- Collapse of a  $>30 M_{\odot}$  star
- Massive stars like these are born with low velocities and live for only  $\sim 10^6$  y
- When they explode, they are still in their host galaxy, in dusty, star-forming regions
- Long GRBs are indeed found close to the centers of their host galaxies
- ISM density allows shock formation
- Host galaxies are still forming stars

## MERGING NEUTRON STARS

- A binary neutron star system may be born with a high kick velocity,  $> 200$  km/s
- The system loses orbital energy by gravitational radiation
- Merger takes place in  $10^8 - 10^9$  y
- By then, the system may be outside the galaxy where it was born
- The tenuous medium might not allow strong shock formation, and therefore the production of intense afterglows
- The host galaxy might not be forming stars at a high rate any more

## Beaming of GRB Emission

- Beaming into a cone of  $5\text{-}10^\circ$  decreases the gamma-ray energies by two orders of magnitude, to  $\sim 10^{51}$  erg
- It also increases the total burst rate by the same factor, but this does not contradict anything we know about star formation and evolution
- How to obtain large energy releases, large luminosities, short variability time scales?
- How does the kinetic energy of the ejecta get converted to electromagnetic radiation?
- Fireball/blast wave model

# Compactness problem

- $\delta T \leq .1 \text{ sec} \Rightarrow$  maximum size of the source  $R \leq c\delta T = 3 \cdot 10^9 \text{ cm.}$

- $E \cong 10^{51} \text{ ergs.}$

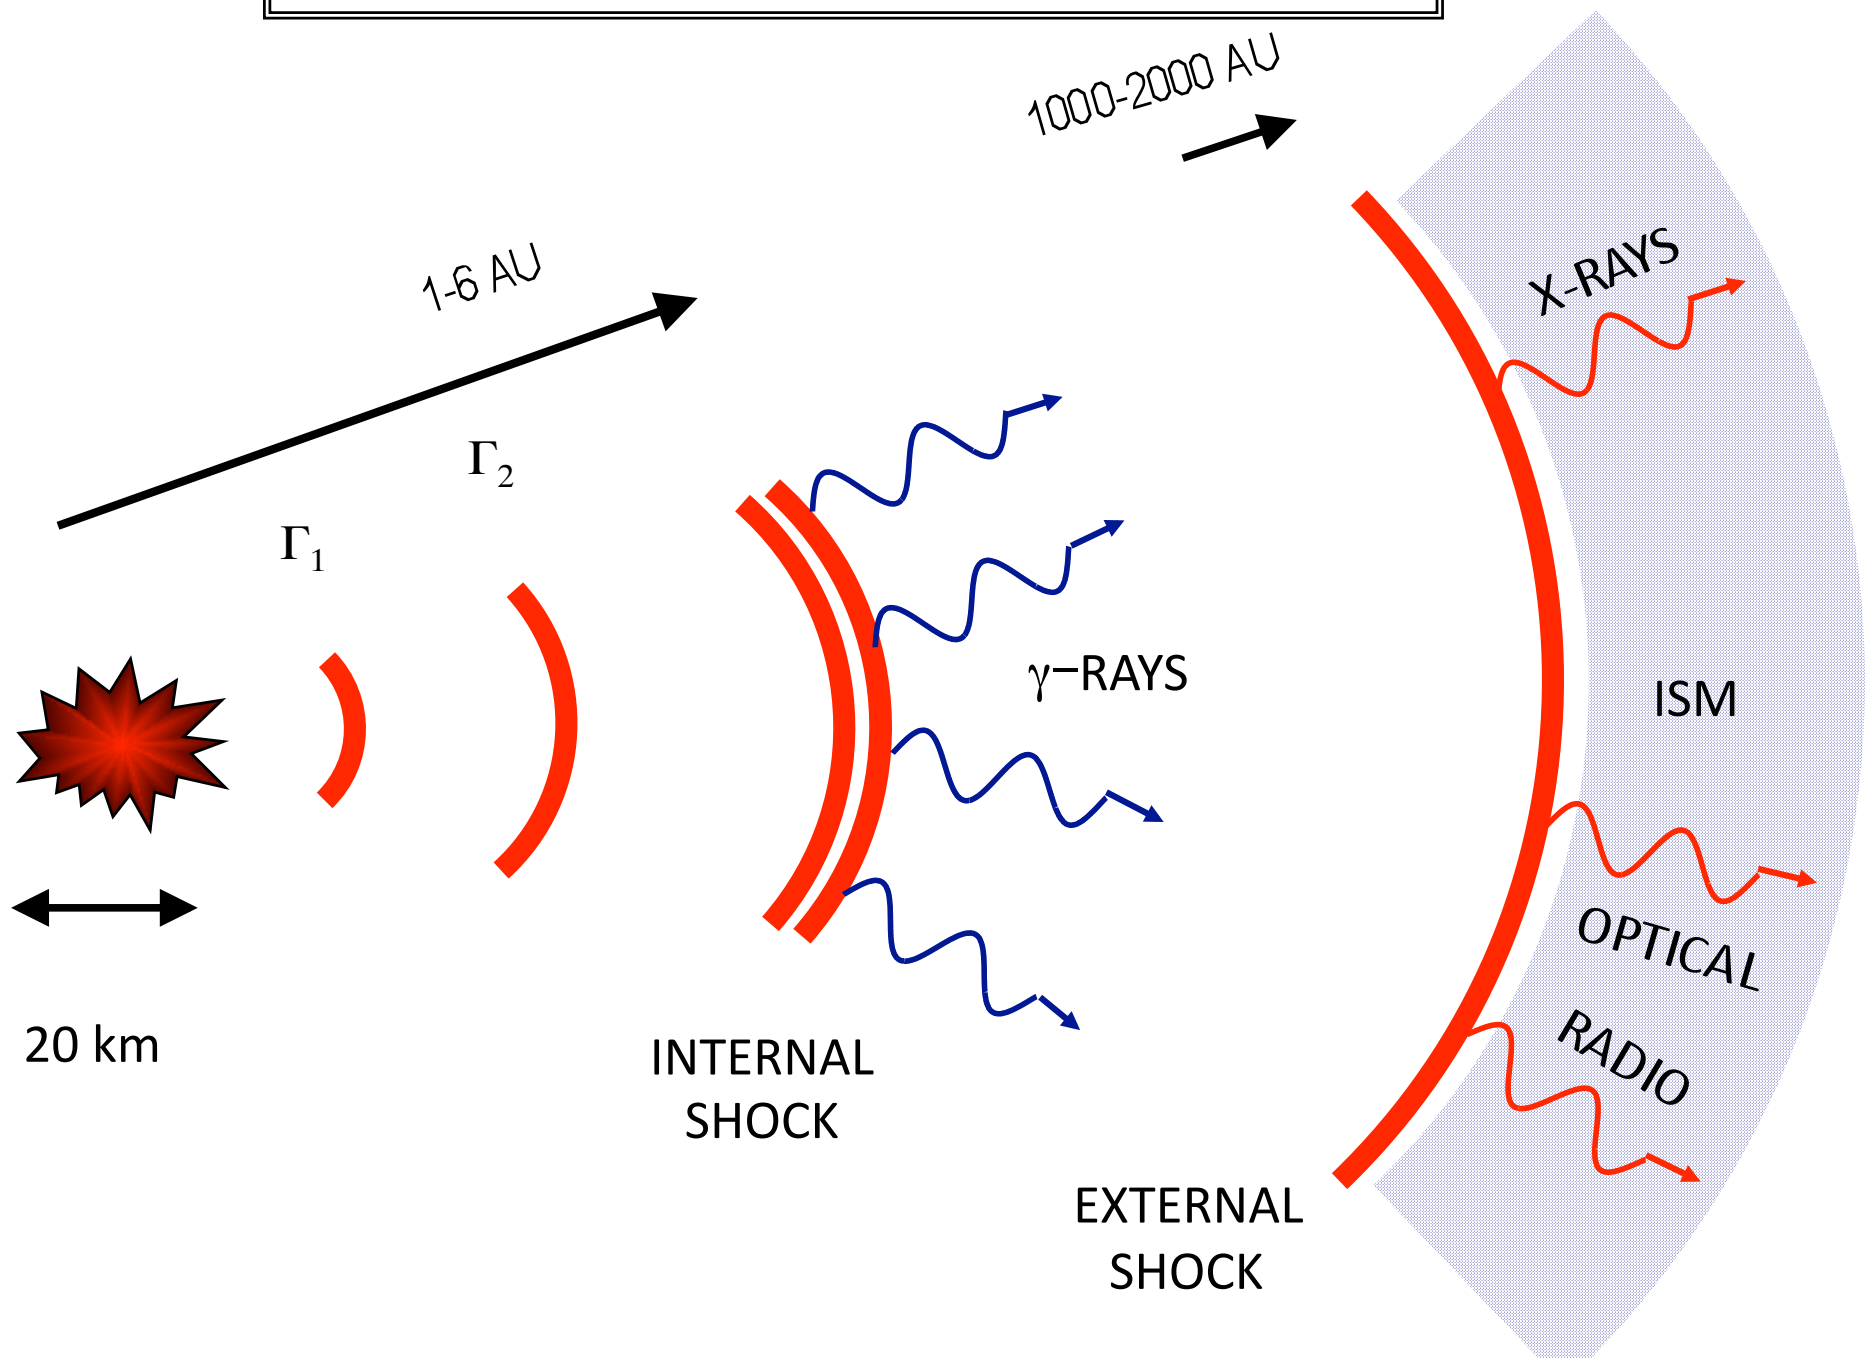

Due to the large photon density and energy  $\gamma\gamma \rightarrow e^+e^-$

**Expected thermal spectrum and no high energy photons**

??

# Fireball/Blast Wave Model

## **What are the X-Ray Flashes?**

- **If XRFs are another manifestation of long GRBs, then are they**
  - 1. GRBs at high redshift?**
  - 2. GRBs observed away from the jet axis?**
  - 3. Explosions with less relativistic ejecta?**
- **We have fairly complete data on one XRF (XRF020903,  $z=0.251$ ); in this case, the answer is compatible with 3 (Soderberg et al. 2004)**
- **Amati relation gives evidence that XRFs and GRBs are part of the same family**

## GRB/Supernovae Rates and Energetics

	GRBs	SUPERNOVAE
<i>UNIVERSE-WIDE RATE</i>	100 - >1000/day	100000/day (all types) 1000-10000/day (Ic)
<i>RATE PER GALAXY</i>	1/10 <sup>5</sup> years	1/50-100 years
<i>ENERGY</i>	10 <sup>51-52</sup> erg	10 <sup>51-52</sup> erg
